Turbulence are the result of from organized convection as warmer air rise in one column of air while colder air sinks in the adjacent column of air. This pattern is repeated over an volume of space...

### Is there a clear separation between chaos and turbulence?

It is now well established that seemingly innocuous dynamical systems, dissipative or not, can produce complicated phase trajectories and, eventually, chaos. There is now an enormous amount of mathematics and physics literature on this subject, little of which has permeated into the chemical engineering community at large.

attractors is what we mean by chaotic behavior. The Lorenz attractor was the first strange attractor, but there are many systems of equations that give rise to chaotic dynamics. Examples of other strange attractors include the Rössler and

### Strange Attractors - Chaos & Fractals

Systems that never reach this equilibrium, such as Lorenz's butterfly wings, are known as strange attractors. Additional strange attractors, corresponding to other equation sets that give rise to chaotic systems, have since been discovered. The Rössler attractor produces a graph that resembles a nautilus shell.

David Ruelle and Floris Takens later predicted, against Landau, that fluid turbulence could develop through a strange attractor, a main concept of chaos theory. Edward Lorenz was an early pioneer of the theory.

### Chaos theory - Wikipedia

Describing the attractors of chaotic dynamical systems has been one of the achievements of chaos theory. A trajectory of the dynamical system in the attractor does not have to satisfy any special constraints except for remaining on the attractor, forward in time. The trajectory may be periodic or chaotic.

Analysis indicates that indeed all series exhibit chaotic behavior, with strange attractors whose (correlation) dimensions range from 4 to 7. These results support the existence of a...

### Stange attractors in atmosphere boundary-layer turbulence

A strange attractor is a concept in chaos theory that is used to describe the behavior of chaotic systems. Unlike a normal attractor, a strange attractor predicts the formation of semi-stable patterns that lack a fixed spatial position.

### What Is a Strange Attractor?

These calculations suggest that this periodic turbulent shear flow is deterministic chaos, and that a strange attractor does underly solutions to the Navier-Stokes equations in such flows. However, the magnitude of the dimension measured invalidates any notion that the global dynamics of such turbulence can be attributed to the interaction of a few degrees of freedom.

Accepting the notion of chaos and strange attractors encourages an acknowledgement of the continual change in social systems, which by extension requires acceptance of 'the inevitability of change' in the many systems that aid agencies operate within and around. Such change should not be viewed as worrying or necessarily negative 22.
